

Running the File Using os Without Exposing API Keys

To run the project without exposing your APIKey and SECRET_KEY directly in the main Python file, follow the steps below in **PowerShell inside VS Code**:

Step 1: Set the Secret Keys as Environment Variables

```
$env:SECRET_KEY="your session key here"  
$env:API_KEY="your API key"
```

Step 2: Verify That the Keys Are Set

```
echo $env:SECRET_KEY echo  
$env:API_KEY
```

If the terminal prints the values of the keys, it means the environment variables have been successfully set.

Step 3: Run the Main File python

```
main.py
```

If everything is configured correctly, the application will start and display a message similar to:

```
Running on http://127.0.0.1:5000
```

Hold **Ctrl + Click** on the URL to open the application in your browser.

Important Note

If an error occurs due to missing environment variables, you can temporarily place the keys directly in the Python file. However, this is **not recommended** because it exposes sensitive information and is not secure.

Using environment variables is the safer and more professional approach.
